## CE 88 Homework 7

In this homework, you will explore how data representation and scaling applied to the explanatory variables may affect the results produced by the predictive algorithms.

**Data.** We will continue working on the mode choice dataset explored in Minilab 7. Minilab 7 contains useful code for processing data and applying a simple knearest neighbors algorithm.

**Problem 1 (5 points).** Assume that the value-of-time (VOT) of all the travelers in the survey is \$20/hour. While it is often observed that VOT is proportional to income (and is approx. one half of the hourly pay rate), we will accept this common estimated value of \$20/hour as a reasonable simplifying assumption for this homework. Implement a data transformation function that scales travel time and costs into common units of either time or \$ (of your choice).

**Problem 2 (5 points).** Apply the k-nearest neighbor method to predict the travel mode using the VOT-scaled variables. Specifically predict the travel mode for a trip where the delta\_travel\_time = 50 minutes and delta\_tavel\_cost = 1.5.

- (a) Report the predicted travel mode using the 20 nearest neighbors to make the prediction.
- (b) Observe the indices of the 20 nearest neighbors, and report whether the nearest neighbors have changed from from the ones found when using the normalized inputs (as in mini-lab 7).

Your submission must contain both a PDF file describing your approach and the results, and the original ipynb.
